BCD to 7-segment latch/decoder/driver

HEF4511B

DESCRIPTION

The HEF4511B is a BCD to 7-segment latch/decoder/driver with four address inputs ( $D_A$  to  $D_D$ ), an active LOW latch enable input ( $\overline{EL}$ ), an active LOW ripple blanking input ( $\overline{BI}$ ), an active LOW lamp test input ( $\overline{LT}$ ), and seven active HIGH n-p-n bipolar transistor segment outputs ( $O_a$  to  $O_g$ ).

When  $\overline{EL}$  is LOW, the state of the segment outputs ( $O_a$  to  $O_g$ ) is determined by the data on  $D_A$  to  $D_D$ . When  $\overline{EL}$  goes HIGH, the last data present on  $D_A$  to  $D_D$  are stored in the latches and the segment outputs remain stable. When  $\overline{LT}$  is LOW, all the segment outputs are HIGH independent of all other input conditions. With  $\overline{LT}$  HIGH, a LOW on  $\overline{BI}$  forces all segment outputs LOW. The inputs  $\overline{LT}$  and  $\overline{BI}$  do not affect the latch circuit.
